CS 240 Programming in C

Array and Pointers

February 21, 2023

Array

Arrays are a kind of data structure that can store a fixed-size sequential collection of elements of the same type or in simple terms - a collection of variables of the same type.

- It is a group of variables of similar data types referred to by a single element.
- Its elements are stored in a contiguous memory location.
- The size of the array should be mentioned while declaring it.
- Array elements are always counted from zero (0) onward.
- Array elements can be accessed using the position of the element in the array.
- The array can have one or more dimensions.

Arrays

40	55	63	17	22	68	89	97	89
0	1	2	3	4	5	6	7	8

<- Array Indices

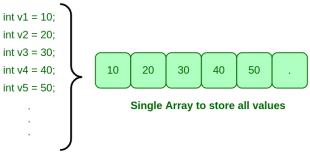

Array Length = 9 First Index = 0 Last Index = 8

1

Why do we need Arrays?

We can use normal variables (v1, v2, v3, \dots) when we have a small number of objects, but if we want to store a large number of instances, it becomes difficult to manage them with normal variables. The idea of an array is to represent many instances in one variable.

Multiple variables to store each value

About arrays

Advantages:

- Code Optimization: we can retrieve or sort the data efficiently.
- Random access: We can get any data located at an index position.

Disadvantages:

Size Limit: We can store only the fixed size of elements in the array.
 It doesn't grow its size at runtime.

Declaring Arrays

Single-dimensional array:

Any C data type may be used as the type, but the array size must be an integer constant greater than zero.

```
type arrayName [ arraySize ];
```

Example:

```
double balance[10];
int account_no[10];
```

Initializing Arrays

	0	1	2	3	4
balance	1000.0	2.0	3.4	7.0	50.0

```
// option 1
    double balance [5] = \{1000.0, 2.0, 3.4, 7.0, 50.0\};
// option 2
    double balance[] = \{1000.0, 2.0, 3.4, 7.0, 50.0\};
// Option 3
    double balance[5] = \{[0] = 1000.0, ... [4] = 50.0\};
// option 4
    double balance[5];
    balance[0] = 1000.0;
    balance[4] = 50.0;
```

```
#include <stdio.h>
int main() {
    int daily Temperatures [7] = \{73, 68, 71, 65, 72, 69, 75\};
    printf("Daily temperatures for the week:\n");
    for (int i = 0: i < 7: i++) {
        printf("Day %d: %d degrees Fahrenheit\n",
            i+1, dailyTemperatures[i]);
    }
    return 0;
```

Passing Array to Function

```
// Formal parameters as a pointer:
    void myFunction(int *param) { ... }

// Formal parameters as a sized array:
    void myFunction(int param[10]) { ... }

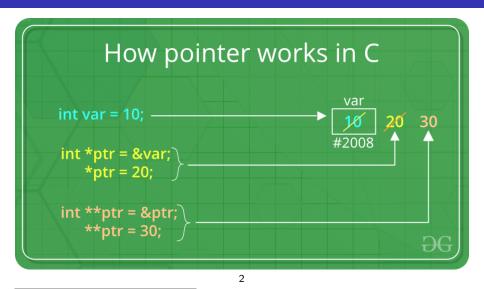

// Formal parameters as an unsized array:
    void myFunction(int param[]) { ... }
```

```
double getAverage(int arr[], int size) {
   double avg, sum = 0;
   for (int i = 0; i < size; ++i) {
      sum += arr[i];
   }
   avg = sum / size;
   return avg;
}</pre>
```

```
#include <stdio.h>
/* function declaration */
double getAverage(int arr[], int size);
int main () {
   /* an int array with 5 elements */
   int balance[5] = {1000, 2, 3, 17, 50};
   double avg;
   /* pass pointer to the array as an argument */
   avg = getAverage( balance, 5 );
   /* output the returned value */
   printf( "Average value is: %f ", avg );
   return 0;
```

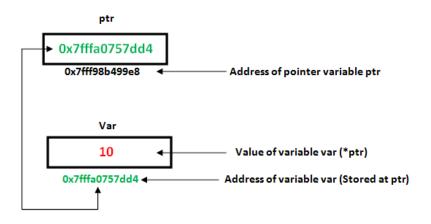

- A pointer is a variable that contains the address of a variable.
- The unary operator & gives the address of an object.
- The & operator only applies to objects in memory: variables and array elements.
- It cannot be applied to expressions, constants, or register variables.

Pointers

²https://www.geeksforgeeks.org/pointers-in-c-and-c-set-1-introduction-arithmetic-and-array/

Aaditya Tamrakar UMass Boston CS 240 February 21, 2023

- The unary operator * is the indirection or dereferencing operator;
- when applied to a pointer, it accesses the object the pointer points to.
- The declaration of a pointer variable is :

```
[datatype] *[variable name]
for example: int *ip;
```

means ip is pointer variable which reference an integer variable. i.e. *ip in an int, and ip is an pointer which stores an address value.

Initialization of a pointer

- There is no legal default value to a pointer variable. You have to initiablize it before using it.
- C guarantees that zero is never a valid address for data, so a pointer of value of zero can be used to signal an abnormal event.
- The symbolic constant NULL is often used in place of zero which is defined in <stdio. h>.
- A pointer has to be initialized to the address of an existing variable before any meaningful using. For example:

```
int i, *ip;
ip = &i; // or int i, *ip = &i;
*ip = 3;
```

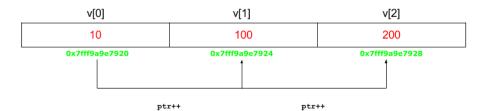

This is illegal

```
int *ip;
*ip = 3;
```

• The *ip in above case is just an integer variable, so it can be put into the expression where integer can be put in. For example:

these are all legal expressions.

Pointers

Pointer as arguments

• Since C passes arguments to functions by value, there is no direct way for the called function to alter a variable in the calling function.

Pointer and Arrays

- In C, there is a strong relationship between pointers and arrays.
- In fact array variable is just one type of pointer. It can be directly assigned to a pointer variable. For example:

```
int a[10] = {-1, -2}, *p = a;
printf("%d\n", *p);
```

• Besides a is just storing the address of the first element of a.

```
int a[10] = {-1}, *p = a;
printf("%d\n", a == &a[0]);
// what will be print out ?
```

And p can also be applied array subscripting like:

```
printf("%d\n", p[1]); // or
printf("%d\n", *(p+1));
```

Pointer and Arrays

- In evaluating a[i], C actually converts it to *(a+i) immediately; the two forms are equivalent.
- &a[i] and a+i are also identical

Pointer and Arrays – One difference

- There is one difference between an array name and a pointer that must be kept in mind.
- A pointer is a variable, so p=a and p++ are legal. But an array name is not a variable; constructions like a=p and a++ are illegal.
- Array name is equivalent to a symbolic constant address value, and it has to be a stack address.
- A pointer can reference to a heap address. We will see how later.

Pointer and Arrays

- As formal parameters in a function definition, char s[] and char *s are equivalent.
- It is preferred of the latter because it says more explicitly that the parameter is a pointer. That's why you see a lot "char *s" in library function headers.
- If one is sure that the elements exist, it is also possible to index backwards in an array; p[-1], p[-2], and so on are syntactically legal,
- ullet But we can not refer to the elements that immediately precede p[0].
- Of course, it is illegal to refer to objects that are not within the array bounds.

Character Pointers and Functions

String constant.

```
char amessage[] = "now is the time"; /* an array */
char *pmessage = "now is the time"; /* a pointer */
```

- amessage is an array. Its individual characters within the array may be changed but amessage will always refer to the same storage.
- pmessage is a pointer, initialized to point to a string constant; the pointer may subsequently be modified to point elsewhere.
- All in all amessange is left value, while pmessage is a right value.
- All in all amessange is left value, while pmessage is a right value.

Pointer Arrays; Pointers to Pointers

```
char *lineptr[3];
lineptr[0] = "hello";
```

lineptr is an array of 3 elements, each element of which is a pointer to a char .

Two-dimensional Arrays

Declaration and initialization.

```
int arr[2][6] = {
     {1, 2, 3, 4, 5, 6},
     {1, 2, 3, 4, 5, 6}
};
```

Three-dimensional Arrays

Declaration and initialization.

```
int x[2][3][2] = {
     { {0, 1}, {2, 3}, {4, 5} },
     { {6, 7}, {8, 9}, {10, 11} }
};
```
